

AMENDMENTS TO THE SPECIFICATION

Kindly amend the last paragraph on page 9 of the disclosure to read as follows (note that the same paragraph was previously amended in an amendment submitted on April 1, 2004):

The last data chunk is followed by a stopper-type separator (or stopper), which is marked as "FM," wherein F represents a hexadecimal numerical value and M represents a predefined identification number, also known as a stopper "magic number." The "FM" separator comprises at least the stopper hexadecimal numerical value and the stopper "magic number." The predefined "magic number" in the stopper is used to verify correctness of the queue management or to check for validity. The stopper ensures that the address in read head register 230 is not incremented beyond that point. If it is reached, the system discontinues reading until such time as additional data is written to memory queue 240 by transmitter 210. When a data message is added, the "FM" field is replaced by an "LP" field.
